Economics And The Life And

The book aims at

presenting technical and

financial features of life

insurance, non-life

insurance, pension plans.

The book has been

planned assuming non-actuarial readers as its “ natural ” target, namely - advanced undergraduate and graduate students in Economics, Business and Finance; - professionals and technicians operating in Insurance and pension areas, whose job may regard investments, risk analysis, financial reporting, etc,

Where To Download

and hence implies a communication with actuarial professionals and managers. Given the assumed target, the book focuses on technical and financial aspects of insurance, however avoiding the use of complex mathematical tools. In this sense, the book can be placed at some “midpoint” of the existing literature,

part of which adopts more formal approaches to insurance problems implying the use of non-elementary mathematics, whereas another part addresses practical questions totally avoiding even simple mathematical tools (which, in our opinion, can conversely provide effective tools for presenting technical and

financial features of the insurance business).

This is part one of a two-volume book on real analysis and is intended for senior undergraduate students of mathematics who have already been exposed to calculus. The emphasis is on rigour and foundations of analysis.

Beginning with the construction of the

number systems and set theory, the book discusses the basics of analysis (limits, series, continuity, differentiation, Riemann integration), through to power series, several variable calculus and Fourier analysis, and then finally the Lebesgue integral. These are almost entirely set in the concrete setting of the

real line and Euclidean spaces, although there is some material on abstract metric and topological spaces. The book also has appendices on mathematical logic and the decimal system. The entire text (omitting some less central topics) can be taught in two quarters of 25 – 30 lectures each. The course material is deeply

intertwined with the exercises, as it is intended that the student actively learn the material (and practice thinking and writing rigorously) by proving several of the key results in the theory.

This work by Zorich on Mathematical Analysis constitutes a thorough first course in real analysis, leading from the

most elementary facts about real numbers to such advanced topics as differential forms on manifolds, asymptotic methods, Fourier, Laplace, and Legendre transforms, and elliptic functions.

The fundamental mathematical tools needed to understand machine learning include

Where To Download

linear algebra, analytic geometry, matrix decompositions, vector calculus, optimization, probability and statistics.

These topics are traditionally taught in disparate courses, making it hard for data science or computer science students, or professionals, to efficiently learn the mathematics. This self-

contained textbook
bridges the gap between
mathematical and
machine learning texts,
introducing the
mathematical concepts
with a minimum of
prerequisites. It uses these
concepts to derive four
central machine learning
methods: linear
regression, principal
component analysis,
Gaussian mixture models

and support vector machines. For students and others with a mathematical background, these derivations provide a starting point to machine learning texts. For those learning the mathematics for the first time, the methods help build intuition and practical experience with applying mathematical concepts.

Every chapter includes worked examples and exercises to test understanding.

Programming tutorials are offered on the book's web site.
